# Chapter 1

## Prolusion

### 1.1 Goal

This report provides a comprehensive overview of a Python project whose goal is to develop and compare different adaptive backpropagation techniques involved in a machine learning process, as Rprop (Resilient BackPropagation).

The project follows the “Empirical evaluation of the improved Rprop learning algorithms” article by Christian Igel and Michel Hüsken (2001).

## 1.2 Software Stack

- Python 3.9.6
- PyTorch 2.6.0

The project is equipped with a `requirements.txt` file which allows for seamless installation of dependencies, by executing `pip install -r requirements.txt`.

## 1.3 Project Structure

```
neuro-backprop-lab/  
├── model/  
├── tester/  
│   ├── tester.py  
│   └── trained_model.pt  
├── trainer/  
│   ├── irpropplus/  
│   ├── rpropminus/  
│   ├── rpropplus/  
│   └── trainer.py  
├── utils/  
├── test_model.py  
└── train_model.py
```

- `model` includes the neural network model architecture.
- `tester` handles the testing flow of the ready-to-use `trained_model.pt`.
- `trainer` handles the examined backpropagation techniques and the training flow of the model, saving it as `trained_model.pt`.
- `utils` offers utility functions designed to support the root project scripts.

## Chapter 2

# Resilient Backpropagation Techniques

Rprop algorithms differ from the classical back-propagation algorithms by the fact that they are independent of the magnitude of the gradient, but only depend on its sign.

## 2.1 Module Overview

The part of the project which is shared across all the examined Rprop techniques is presented as follows.

### 2.1.1 Model

This class represents the artificial neural network model architecture to be trained and tested.

It is a shallow network based on `torch.nn.Module`<sup>1</sup> class. Its layers are fully connected using `torch.nn.Linear(.)` and they feed forward as follows:

1. the first layer flattens the input MNIST image, by transforming it from a multidimensional vector to a 784-sized (since a  $28 \times 28$  sized image is manipulated) one-dimensional vector;
2. the hidden layer receives the transformed vector and processes it into a 128-sized vector with a ReLU activation function to introduce non-linearity, a choice that was the result of empirical experiments;
3. the output layer extracts the final predictions by transforming the 128-sized vector into a 10-sized vector, which corresponds to the number of possible classes for classification.

### **2.1.2 Tester**

### **2.1.3 Trainer**

### **2.1.4 Utils**

## **2.2 Implementations**

### **2.2.1 Rprop-**

This is Rprop-.

### **2.2.2 Rprop+**

This is Rprop+.

## **2.3 Comparisons**

Here I will show comparisons.
