Chapter 1

Prolusion

1.1 Goal

This report provides a comprehensive overview of a Python project whose goal is to develop and compare different adaptive backpropagation techniques involved in a machine learning process, as Rprop (Resilient BackPropagation). MNIST is the target of the learning model.

The project follows the "Empirical evaluation of the improved Rprop learning algorithms" article by Christian Igel and Michel Hüsken (2001).

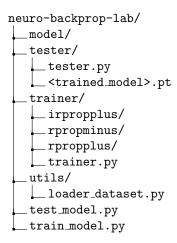

1.2 Software Stack

- Python 3.9.6
- \bullet PyTorch 2.6.0

The project is equipped with a requirements.txt file which allows for seamless installation of dependencies, by executing pip install -r requirements.txt.

3

1.3 Project Structure

- model includes the neural network model architecture.
- \bullet tester handles the testing flow of the ready-to-use trained_model>.pt.
- trainer handles the examined backpropagation techniques and the training flow of the model, saving it as <trained_model>.pt.
- \bullet utils offers utility functions designed to support the root project scripts.

Chapter 2

Module Overview

The part of the project which is shared across all the examined Rprop techniques is presented as follows.

2.1 Train Model

This script runs the training flow of the model and saves the model for future testing phase.

Algorithm 1: train_model.py

```
model \leftarrow newModel() \\ criterion, optimizer, epochs, train\_set, eval\_set \leftarrow get\_configuration() \\ Trainer.traineval(model, criterion, optimizer, train\_set, eval\_set, epochs)
```

2.2. TEST MODEL 7

2.2 Test Model

This script runs the test flow of the model.

Algorithm 2: test_model.py

 $model, optimizer \leftarrow load_model() \\ criterion, test_set \leftarrow get_configuration()$

 $Tester.test(model, criterion, test_set)$

2.3 Model

This class, model.py, represents the artificial neural network model architecture to be trained and tested. What follows are empirical choices that are the result of various experiments.

The model is a shallow network based on torch.nn.Module¹ class. Its three layers are fully connected using torch.nn.Linear(.) and they feed forward as follows:

- 1. the first layer flattens the input MNIST image, by transforming it from a multidimensional vector to a 784-sized (since a 28×28 -sized image is manipulated) one-dimensional vector;
- 2. the hidden layer receives the transformed vector and processes it into a 128-sized vector with a ReLU activation function to introduce non-linearity;
- 3. the output layer extracts the final predictions by transforming the 128-sized vector into a 10-sized vector, which corresponds to the number of possible classes for classification.

¹https://pytorch.org/docs/stable/generated/torch.nn.Module.html (accessed 2025)

2.4. TRAINER 9

2.4 Trainer

This class, trainer.py, is responsible for training the model and saving it for future testing phase. Data retrieval is addressed in subsection 2.6.1.

Algorithm 3: trainer.py

```
Function traineval (model, criterion, optimizer, train_set, eval_set, epochs):
    foreach epoch \in epochs do
         train\_loss\_avg\_train\_accuracy \leftarrow
           train(model, criterion, optimizer, train\_set, train\_loss\_avgs, train\_accuracies)
         eval\_loss\_avg, eval\_accuracy \leftarrow eval(model, criterion, eval\_set, eval\_loss\_avgs, eval\_accuracies)
         \mathbf{if}\ eval\_loss\_avg < eval\_loss\_avg\_prev\ \mathbf{then}
            save model(model)
         end
    end
    \textbf{return} \ train\_loss\_avgs, train\_accuracies, eval\_loss\_avgs, eval\_accuracies
Function train(model, criterion, optimizer, train_set, loss_averages, accuracies):
    \mathbf{foreach}\ batch \in train\_set\ \mathbf{do}
         labels, loss, outputs \gets trainstep(model, criterion, optimizer, batch)
          total\_correct, total\_loss, total\_samples \leftarrow
           gather\_metrics(labels, loss, outputs, total\_correct, total\_loss, total\_samples)
    \mathbf{end}
    loss\_average, accuracy \leftarrow
      compute\_metrics(total\_correct, total\_loss, total\_samples, loss\_averages, loss\_accuracies)
    return loss_average, accuracy
return
Function trainstep(model, criterion, optimizer, batch):
    inputs, labels \leftarrow batch
    outputs \leftarrow model(inputs)
    loss \gets criterion(outputs, labels)
    loss.compute\_gradients()
    optimizer.step()
    {\bf return}\ labels, loss, outputs
return
Function eval(model, criterion, eval_set, loss_averages, accuracies):
    \mathbf{foreach}\ batch \in eval\_set\ \mathbf{do}
         labels, loss, outputs \leftarrow evalstep(model, criterion, batch)
         total\_correct, total\_loss, total\_samples \leftarrow
           gather\_metrics(labels, loss, outputs, total\_correct, total\_loss, total\_samples)
    end
    loss\_average, accuracy \gets
      compute\_metrics(total\_correct, total\_loss, total\_samples, loss\_averages, accuracies)
    return loss_average, accuracy
return
Function evalstep(model, criterion, batch): |inputs, labels \leftarrow batch|
    outputs \leftarrow model(inputs)
    loss \leftarrow criterion(outputs, labels)
    {\bf return}\ labels, loss, outputs
return
```

2.5. TESTER 11

2.5 Tester

return

This class, tester.py, is responsible for loading and evaluating a pre-trained model on unseen data.

```
Algorithm 4: tester.py

Input : model, criterion, test_set

Function test(model, criterion, test_set):

| foreach batch ∈ test_set do | labels, loss, outputs ← eval(model, criterion, batch) | total_correct, total_loss, total_samples ← gather_metrics(labels, loss, outputs) | end | loss_average, accuracy ← compute_metrics(total_correct, total_loss, total_samples) | return

Function eval(model, criterion, batch):
| inputs, labels ← batch | outputs ← model(inputs) | loss ← criterion(outputs, labels) | return labels, loss, outputs
```

2.6 Utils

2.6.1 Loader Dataset

This class, loader-dataset.py, is responsible for the methodology employed for data retrieval. It is the module that takes the most importance of the utils package, so it was worth describing it.

The method used to get the data is holdout, there is more than one function involved in this.

Algorithm 5: loader_dataset.py

```
 \begin{aligned} & \textbf{Function} \ get datasettraineval (dataset\_size\_train, \ batch\_size\_train, \ dataset\_size\_eval, \\ & batch\_size\_eval) \colon \\ & | \ learning\_set \leftarrow get\_MNIST\_dataset (learn\_mode = True) \\ & \ dataset\_train, \ dataset\_eval \leftarrow \\ & \ split(learning\_set, \ dataset\_size\_train, \ batch\_size\_train, \ dataset\_size\_eval, \ batch\_size\_eval) \\ & \ \textbf{return} \ \ dataset\_train, \ dataset\_eval \\ & \ \textbf{return} \end{aligned}
```

As planned, the learning data is completely separated from the testing data with the learn_mode parameter.

The learning set is, in turn, split into the train set for the training phase and in the eval set for the evaluation phase. Finally, the train set undergoes a data shuffle, this should make the train phase more robust. The eval set comes in handy to avoid overfitting.

It is also important to note that the MNIST allocates 60,000 samples for training and 10,000 for testing.

Chapter 3

Resilient Backpropagation Techniques

Rprop algorithms differ from the classical back-propagation algorithms by the fact that they are independent of the magnitude of the gradient, but depend on its sign only.

3.1 Implementations

Recall that the main concern of the documentation is readability. Hence, pseudocode and actual code implementations may slightly differ, as the Python scripting language allows for significant performance improvements through the use of native structures. These differences clearly don't affect the functionality of the implementations.

Each Rprop algorithm that will be described corresponds to a specialized torch.optim.Optimizer.step()¹ class method.

An Rprop algorithm is intended to perform the following steps:

- 1. Compute the gradient of the error function with respect to the model weights.
- 2. Update the step size based on a conditional logic of the current and previous gradient sign:

$$\Delta_{ij}^{curr} = \begin{cases} \min(\eta^+ \cdot \Delta_{ij}^{prev}, \Delta_{\max}) & \text{if } \frac{\partial E}{\partial w_{ij}}^{curr} \cdot \frac{\partial E}{\partial w_{ij}}^{prev} > 0 \\ \max(\eta^- \cdot \Delta_{ij}^{prev}, \Delta_{\min}) & \text{if } \frac{\partial E}{\partial w_{ij}}^{curr} \cdot \frac{\partial E}{\partial w_{ij}}^{prev} < 0 \\ \Delta_{ij}^{prev} & \text{otherwise} \end{cases}$$

- 3. Update the step size direction using either weight-backtracking or the gradient sign.
- 4. Update weights with the step size direction.

Subsequently, each variant of the algorithm implements its own adaptation of this general process.

¹https://pytorch.org/docs/main/optim.html (accessed 2025)

3.1.1 Rprop without Weight-Backtracking

This Rprop version, also said Rprop⁻, updates the step size direction with the gradient sign only. Even though the gradient-product case resulting in zero is a no-op, it is kept for readability and consistency with other algorithms.

Algorithm 6: RpropMinus.step()

$$\begin{split} & \textbf{for } parameter \in parameters \ \textbf{do} \\ & \textbf{if } \frac{\partial E}{\partial w_{ij}}^{curr} \cdot \frac{\partial E}{\partial w_{ij}}^{prev} > 0 \ \textbf{then} \\ & \Delta_{ij}^{curr} = \min(\eta^+ \cdot \Delta_{ij}^{prev}, \Delta_{\max}) \\ & \textbf{end} \\ & \textbf{if } \frac{\partial E}{\partial w_{ij}}^{curr} \cdot \frac{\partial E}{\partial w_{ij}}^{prev} < 0 \ \textbf{then} \\ & \Delta_{ij}^{curr} = \max(\eta^- \cdot \Delta_{ij}^{prev}, \Delta_{\min}) \\ & \textbf{end} \\ & \textbf{if } \frac{\partial E}{\partial w_{ij}}^{curr} \cdot \frac{\partial E}{\partial w_{ij}}^{prev} = 0 \ \textbf{then} \\ & \Delta_{ij}^{curr} = \Delta_{ij}^{prev} \\ & \textbf{end} \\ & \Delta w_{ij}^{curr} = -\operatorname{sign}(\frac{\partial E}{\partial w_{ij}}^{curr}) \cdot \Delta_{ij}^{curr} \\ & w_{ij}^{curr} = w_{ij}^{prev} + \Delta w_{ij}^{curr} \\ & \textbf{end} \\ \end{split}$$

3.1.2 Rprop with Weight-Backtracking

This Rprop version, also said Rprop⁺, updates the step size direction with the gradient sign when the gradient product is greater than or equal to zero. In the other case the algorithm performs a weight-backtracking, formally $\Delta w_{ij}^{curr} = -\Delta w_{ij}^{prev}$, then the current gradient is set to zero in order to activate the gradient-product case resulting in zero in the next iteration.

Algorithm 7: RpropPlus.step()

$$\begin{split} & \textbf{for } parameter \in parameters \ \textbf{do} \\ & \textbf{if } \frac{\partial E}{\partial w_{ij}}^{curr} \cdot \frac{\partial E}{\partial w_{ij}}^{prev} > 0 \ \textbf{then} \\ & \Delta_{ij}^{curr} = \min(\eta^+ \cdot \Delta_{ij}^{prev}, \Delta_{\max}) \\ & \Delta w_{ij}^{curr} = -\operatorname{sign}(\frac{\partial E}{\partial w_{ij}}^{curr}) \cdot \Delta_{ij}^{curr} \\ & \textbf{end} \\ & \textbf{if } \frac{\partial E}{\partial w_{ij}}^{curr} \cdot \frac{\partial E}{\partial w_{ij}}^{prev} < 0 \ \textbf{then} \\ & \Delta_{ij}^{curr} = \max(\eta^- \cdot \Delta_{ij}^{prev}, \Delta_{\min}) \\ & \Delta w_{ij}^{curr} = -\Delta w_{ij}^{prev} \\ & \frac{\partial E}{\partial w_{ij}}^{curr} = 0 \\ & \textbf{end} \\ & \textbf{if } \frac{\partial E}{\partial w_{ij}}^{curr} \cdot \frac{\partial E}{\partial w_{ij}}^{prev} = 0 \ \textbf{then} \\ & \Delta_{ij}^{curr} = \Delta_{ij}^{prev} \\ & \Delta w_{ij}^{curr} = -\operatorname{sign}(\frac{\partial E}{\partial w_{ij}}^{curr}) \cdot \Delta_{ij}^{curr} \\ & \textbf{end} \\ & w_{ij}^{curr} = w_{ij}^{prev} + \Delta w_{ij}^{curr} \end{split}$$

3.1.3 Improved Rprop with Weight-Backtracking

This Rprop version, also said IRprop⁺, extends the one described in subsection 3.1.2.

The only modification concerns the gradient-product case resulting in less than zero: weight-backtracking is adopted only if the current error is greater than the previous error (this is what is meant by 'improved'), otherwise the step size direction is set to zero.

Algorithm 8: IRpropPlus.step()

$$\begin{split} & \text{for } parameter \in parameters \text{ do} \\ & \text{if } \frac{\partial E}{\partial w_{ij}}^{curr} \cdot \frac{\partial E}{\partial w_{ij}}^{prev} > 0 \text{ then} \\ & \Delta_{ij}^{curr} = \min(\eta^+ \cdot \Delta_{ij}^{prev}, \Delta_{\max}) \\ & \Delta w_{ij}^{curr} = -\operatorname{sign}(\frac{\partial E}{\partial w_{ij}}^{curr}) \cdot \Delta_{ij}^{curr} \\ & \text{end} \\ & \text{if } \frac{\partial E}{\partial w_{ij}}^{curr} \cdot \frac{\partial E}{\partial w_{ij}}^{prev} < 0 \text{ then} \\ & \Delta_{ij}^{curr} = \max(\eta^- \cdot \Delta_{ij}^{prev}, \Delta_{\min}) \\ & \text{if } E^{curr} > E^{prev} \text{ then} \\ & \Delta w_{ij}^{curr} = -\Delta w_{ij}^{prev} \\ & \text{else} \\ & \Delta w_{ij}^{curr} = 0 \\ & \text{end} \\ & \frac{\partial E}{\partial w_{ij}}^{curr} \cdot \frac{\partial E}{\partial w_{ij}}^{prev} = 0 \text{ then} \\ & \Delta_{ij}^{curr} = \Delta_{ij}^{prev} \\ & \Delta w_{ij}^{curr} = -\operatorname{sign}(\frac{\partial E}{\partial w_{ij}}^{curr}) \cdot \Delta_{ij}^{curr} \\ & \text{end} \\ & w_{ij}^{curr} = w_{ij}^{prev} + \Delta w_{ij}^{curr} \end{split}$$

3.2. COMPARISONS 17

3.1.4 Rprop with Weight-Backtracking by PyTorch

This is Rprop+ by PyTorch.²

3.2 Comparisons

Here I will show comparisons.
